December 9, 2024

1 Key Terms

- **Turing Test:** An operational test for intelligent behavior, where a human evaluator engages in natural language conversations with both a human and a machine, attempting to distinguish them. The machine passes if the evaluator cannot reliably identify it as such.
- **Chinese Room Argument:** A thought experiment that challenges the validity of the Turing Test as a measure of true intelligence, arguing that a system can pass the test without possessing genuine understanding.
- **Minimax Search:** A decision-making algorithm used in game playing, where the algorithm searches the game tree to find the optimal move for the current player, assuming the opponent will also play optimally.
- **Alpha-Beta Pruning:** An optimization technique used to reduce the search space in Minimax search by eliminating branches that cannot affect the optimal decision.
- **Perceptron:** A fundamental unit in neural networks, consisting of weighted inputs, a summation node, and an activation function that produces an output.
- **Reinforcement Learning:** A type of machine learning where an agent learns to make decisions by interacting with an environment and receiving rewards or penalties based on its actions.
- **ImageNet Dataset:** A large database of images used for training and benchmarking computer vision models.
- **AI Stack:** A layered representation of the components and subfields within artificial intelligence, including machine learning, search algorithms, computer vision, and human-computer interaction.

2 Problem Types

- **Understanding the Nature of Intelligence:** This problem explores the definition and characteristics of intelligence, both human and artificial. Different perspectives and definitions of AI are examined.
- **Evaluating Intelligent Behavior:** This problem focuses on developing methods for assessing whether a machine exhibits intelligent behavior. The Turing Test and its limitations are discussed, along with counterarguments like Searle's Chinese Room argument.
- **Overcoming the Limits of Search:** This problem addresses the computational challenges of exhaustive search in complex games like chess and Go. The exponential growth of search space is highlighted, leading to the need for machine learning techniques to supplement search.
- **Addressing AI Safety and Ethical Concerns:** This problem explores the potential risks and ethical implications of AI systems. Examples include bias in algorithms and the vulnerability of neural networks to adversarial attacks.

- **Bridging the Gap Between Different AI Domains:** This problem investigates the commonalities and differences between seemingly disparate AI tasks, such as game playing and speech synthesis. The shared algorithmic components and challenges are analyzed.
- **Understanding the Challenges of Autonomous Systems:** This problem examines the complexities involved in building autonomous systems, such as self-driving cars. The reasons for choosing autonomous vehicles as an AI Grand Challenge are explored.
- **Developing Effective Game-Playing Algorithms:** This problem focuses on designing algorithms for playing games, considering aspects like state representation, action selection, and opponent modeling. Minimax search and Alpha-Beta pruning are discussed as key techniques.

3 Algorithm Solutions

- **Minimax Search:** A recursive algorithm for two-player zero-sum games that explores the game tree to find the best move for the current player, assuming the opponent also plays optimally. It alternates between maximizing the score for the current player and minimizing the score for the opponent.
- **Alpha-Beta Pruning:** A technique to reduce the search space in Minimax search by avoiding the evaluation of branches that cannot affect the optimal decision. It uses alpha (best value for the maximizing player) and beta (best value for the minimizing player) values to prune branches.
